A temperature gradient on the Central Pacific Ocean controls the rain and the wind direction

El Niño and Rainfall

El Niño conditions in the tropical Pacific are known to shift rainfall patterns in many different parts of the world. Although they vary somewhat from one El Niño to the next, the strongest shifts remain fairly consistent in the regions and seasons shown on the map below.

www.pmel.noaa.gov (01/07/2017)

The climatic cycle

- Unstable climatic conditions
- Germination burst
- High competition

Game over

Insert Coin

- High stable climatic conditions
- Slow and steady growth
- Survival mechanism

ng the ENSO

STUDY SITE LOCATION (near the 1+2 region)

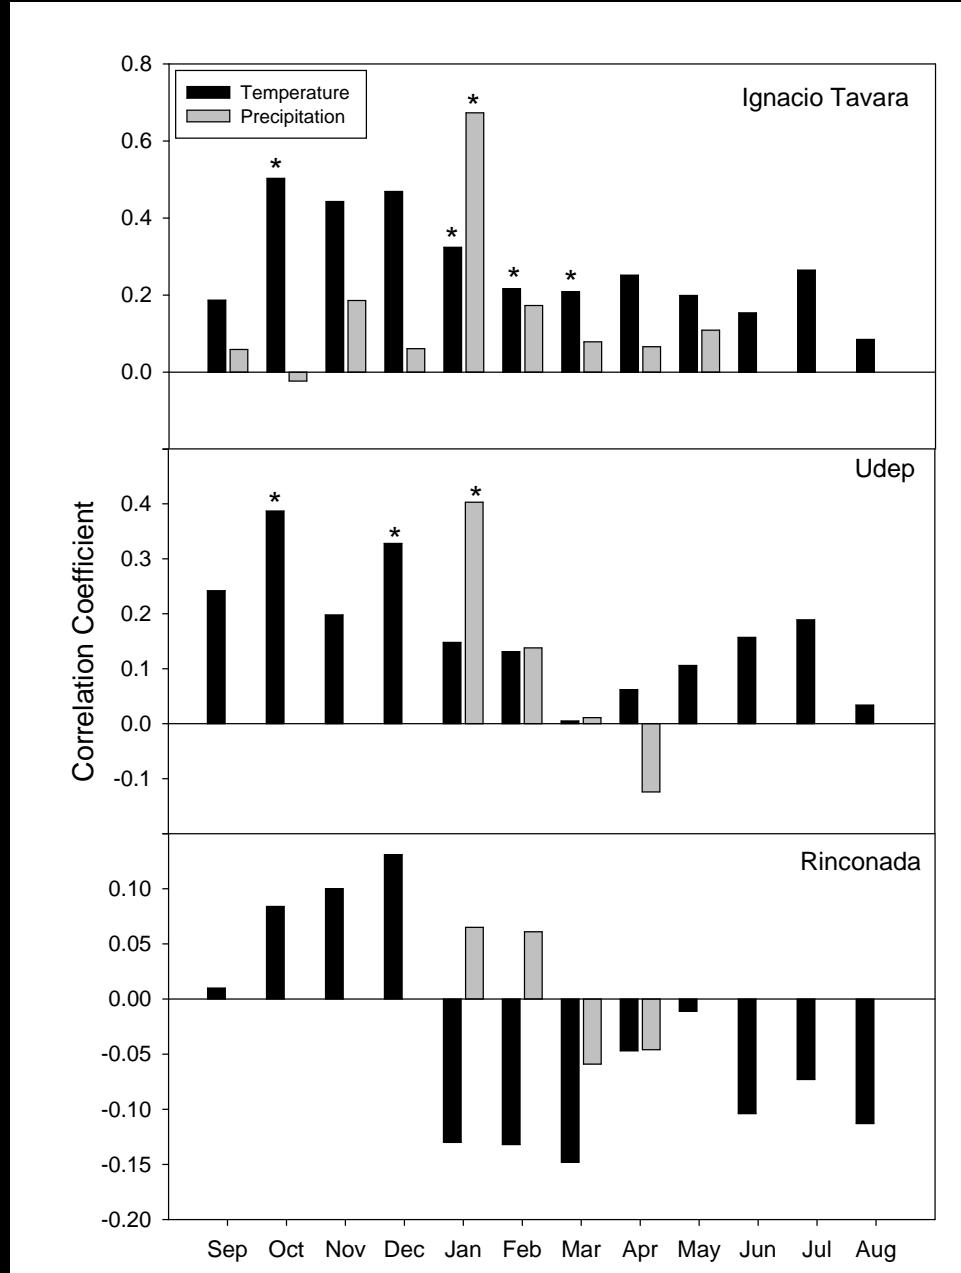

Inland populations are more ENSO-dependant than coastal locations

Dendrochronological results shows a high temporal and spatial variation of the ENSO

Winter temperature is a reliable indicator of ENSO intensity

Salazar et al. unpublished

Growth and Survival during the dry phase

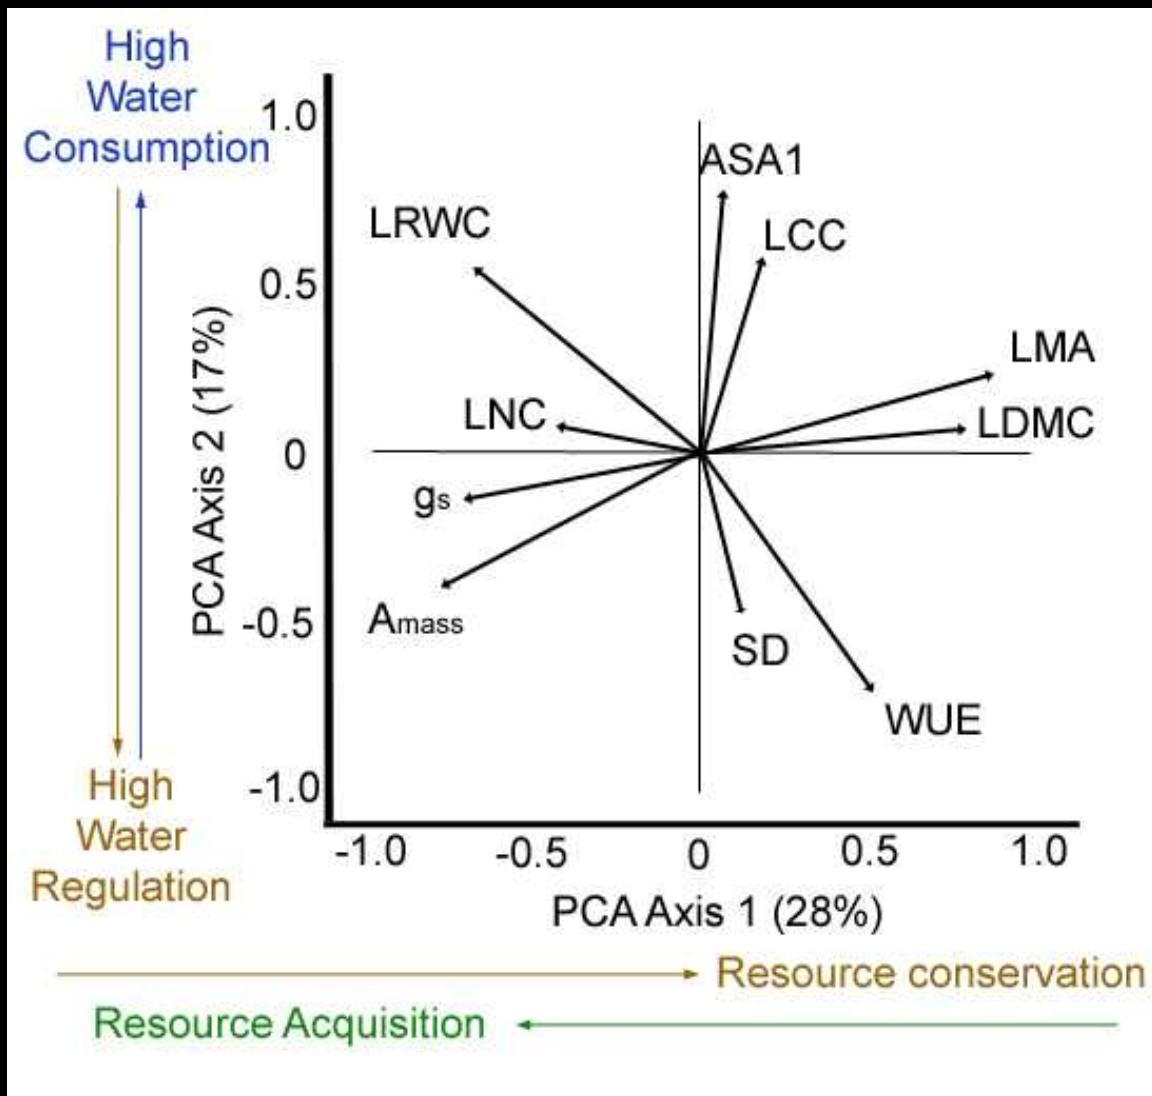

Leaf functional traits as indicators of plant functioning

- Net photosynthesis
- LMA
- Leaf nutrient content
- LRWC
- Leaf stomatal size
- Soil measurements

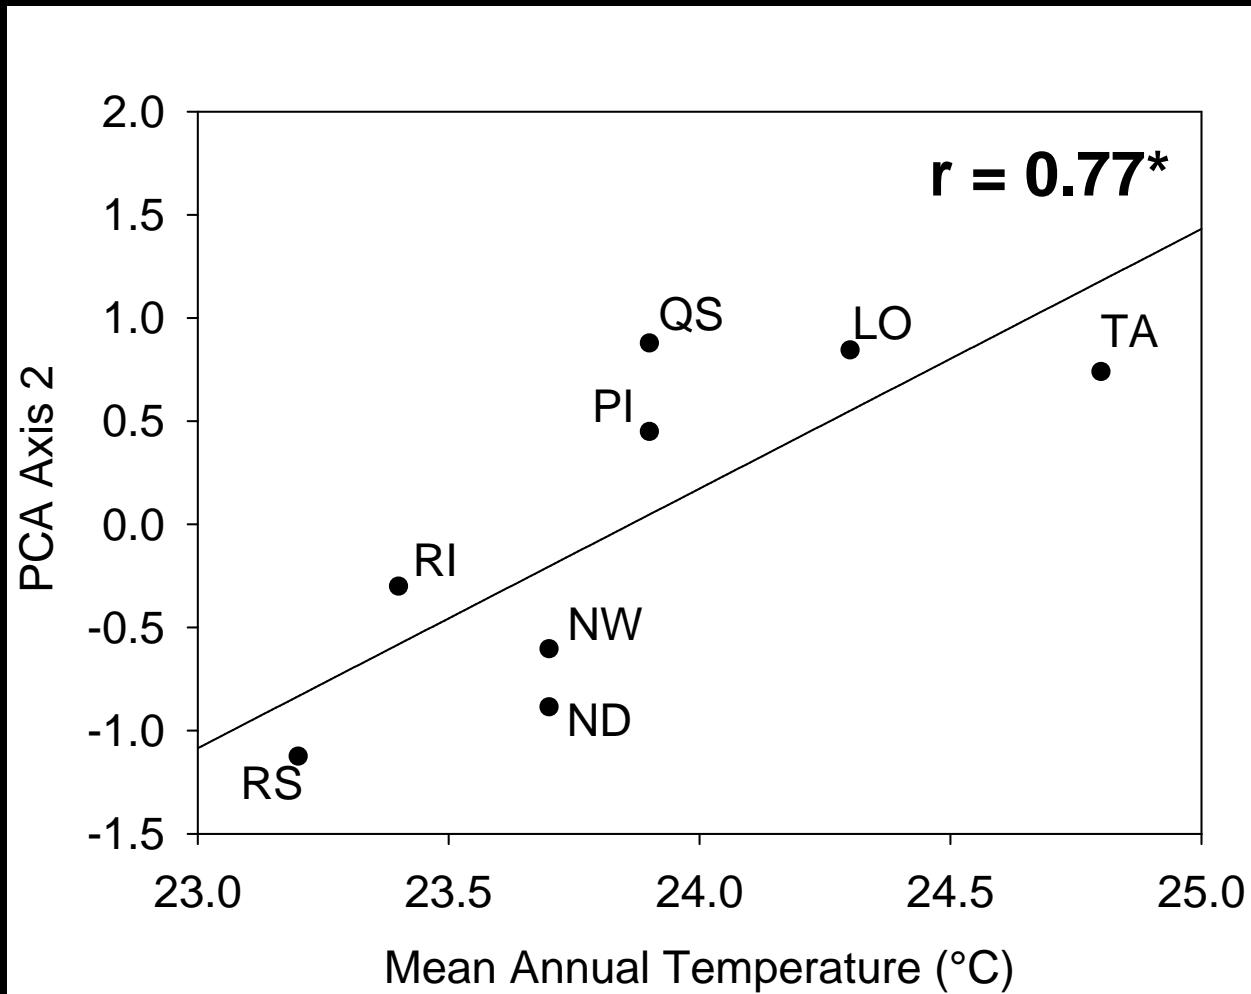

Osnas et al. Science (2013)

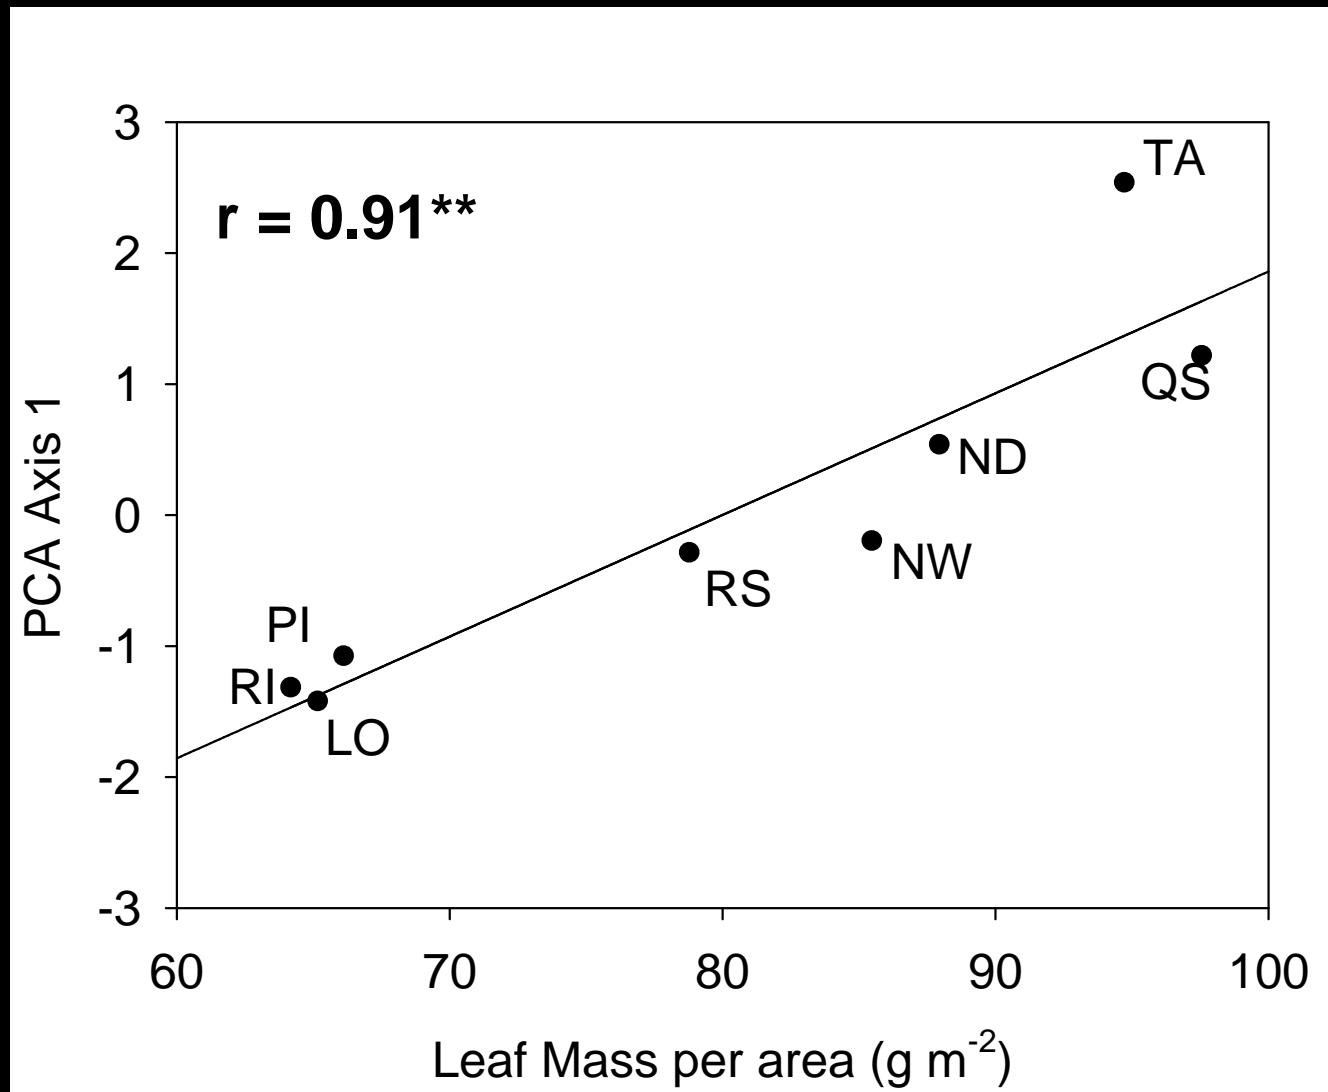

Principal component analysis

Temperature plays an important role in plant functioning during the dry season

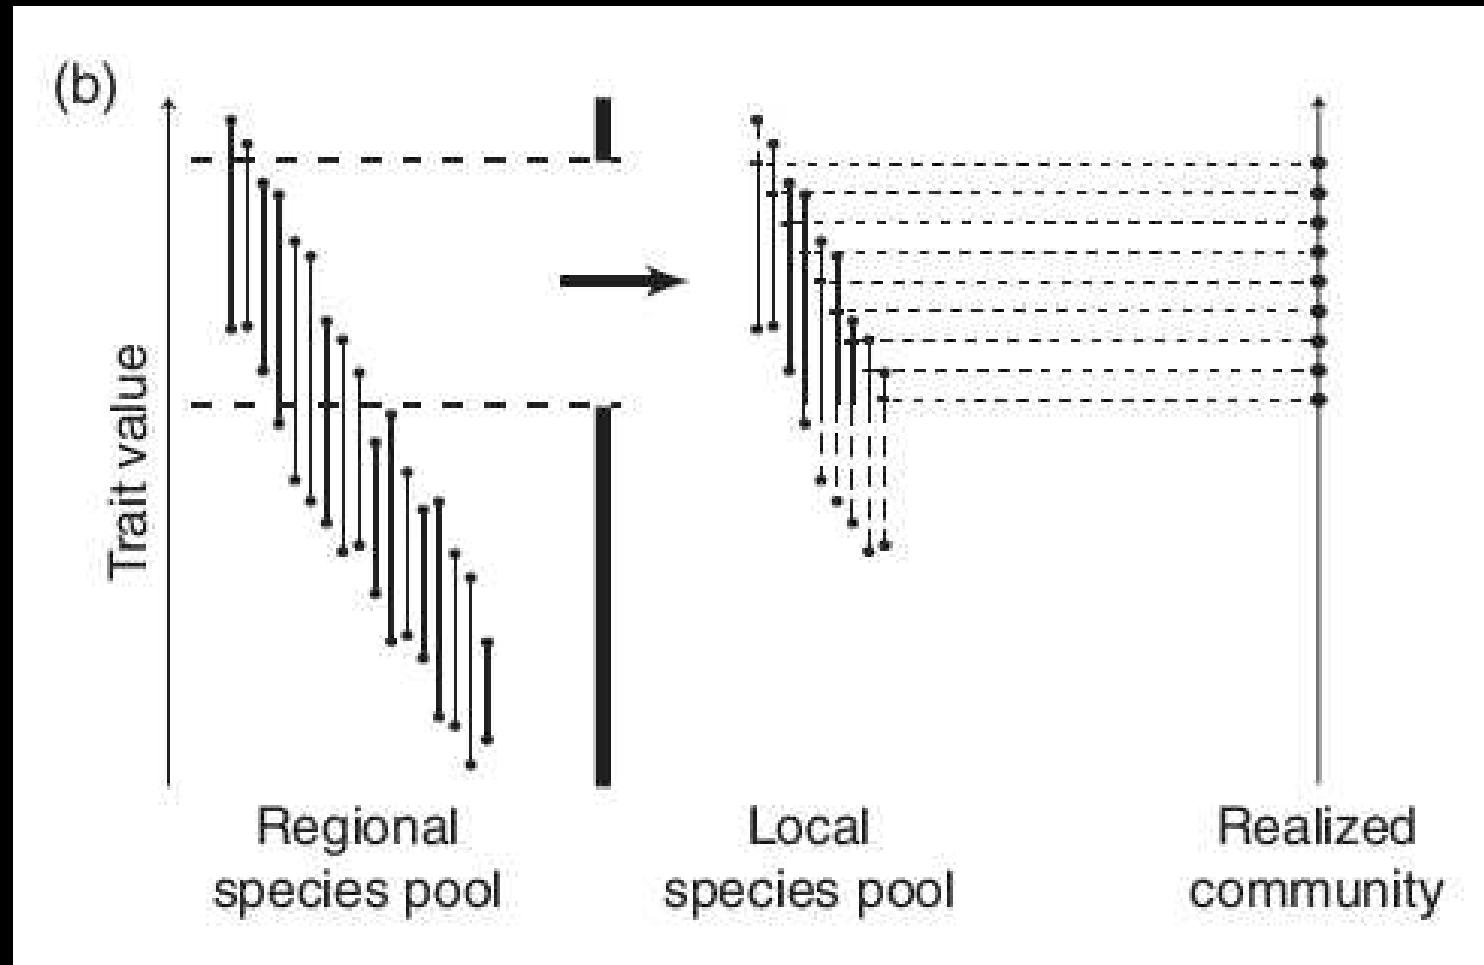

Leaf morphology is the main driver

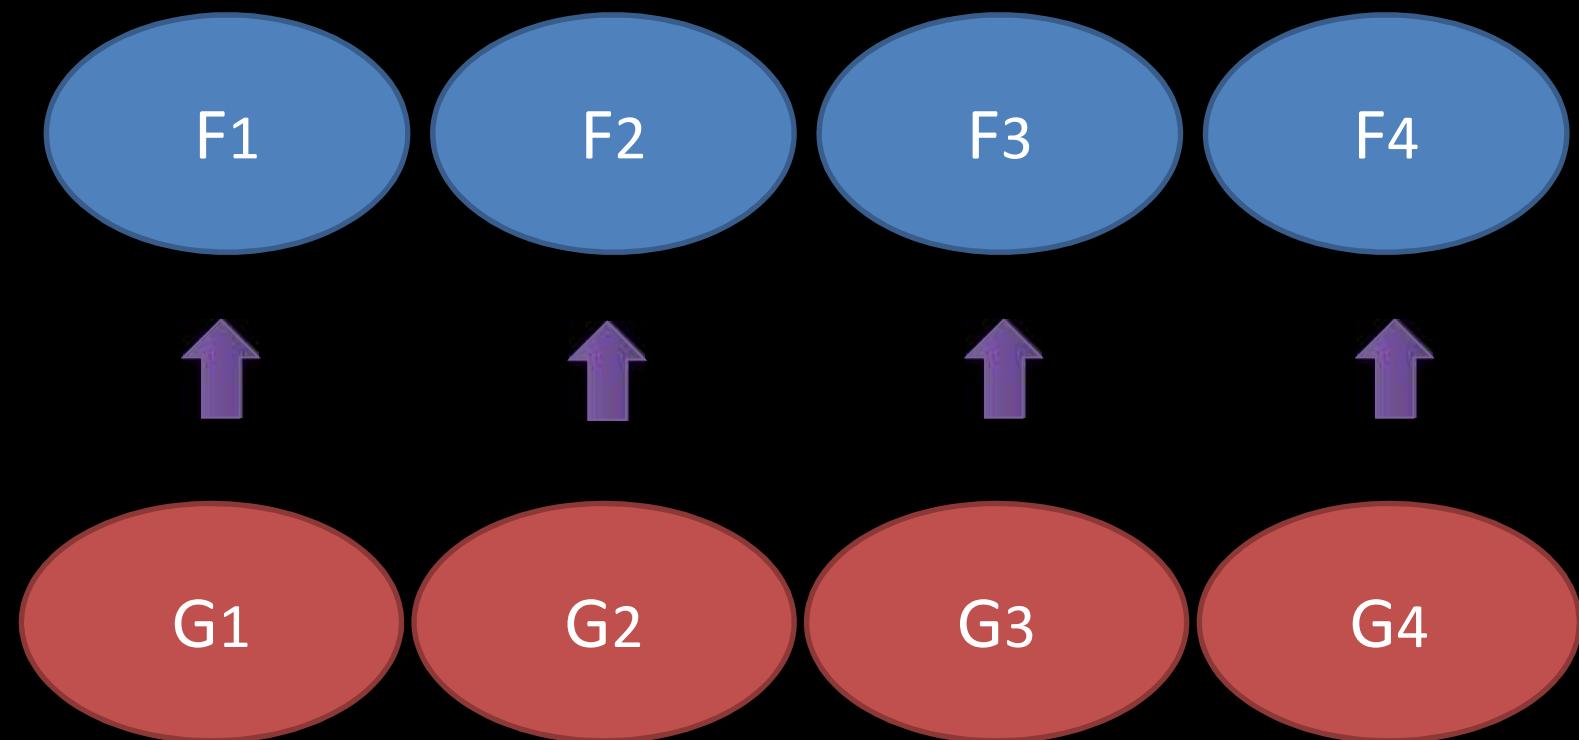

- The *P. pallida* forest have a **high functional variability** at macro and micro scale depending of the trait
- **Nutrient consumption** and **water regulation** are the most important factors in this ecosystem
- Functional variability is controlled by **mean temperature** and **leaf morphology**
- But what about the rain??

La variabilidad poblacional esta mediada por factores de alta cobertura geográfica

Jung et al Journal of Ecology 2010

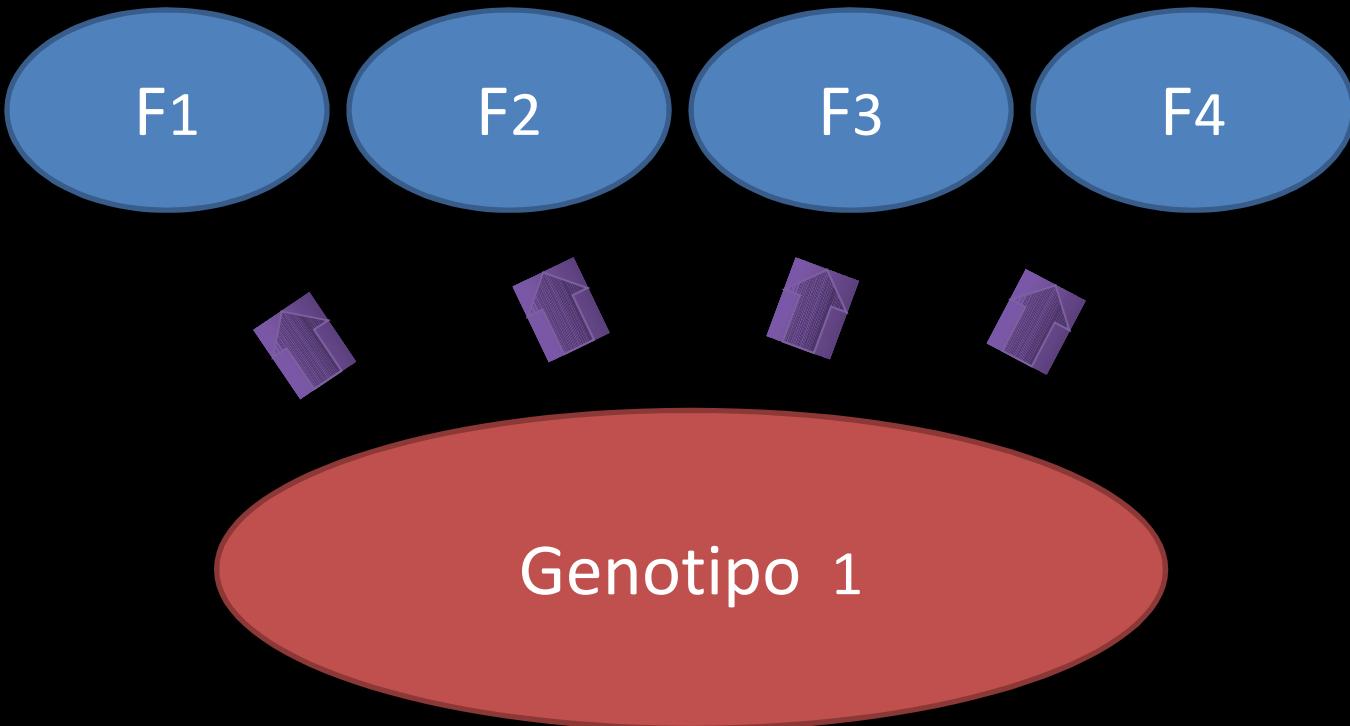

Intrapecific variability

La **variabilidad intraespecífica** depende de la variabilidad genética y de la plasticidad fenotípica.

Phenotypic plasticity

Es la capacidad de un genotipo para expresar fenotipos diferentes bajo condiciones externas diferentes (Valladares et al. 2006).

Greenhouse experiment

- Tratamiento hidrico
 - R0 = 40% CC
 - R1 = 80% CC
- Tratamiento poblacional
 - 7 poblaciones
- 8 replicas por tratamiento
- N = 112

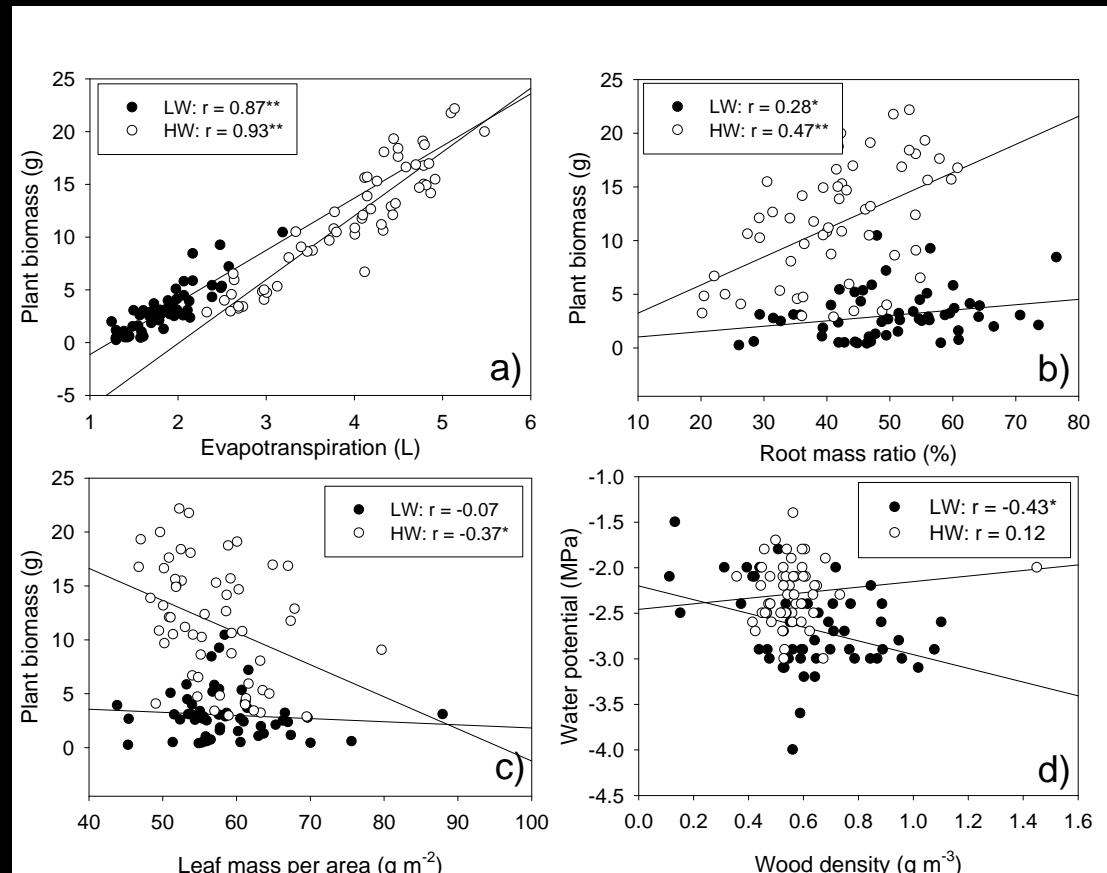

Low vs High water availability

Just like another grass species, an increase in water availability will water consumption and plant biomass

RMR is crucial to increase plant biomass in both scenarios

LMA variability is more relevant under high water conditions

Water transport is related to wood morphology under dry conditions

Population differences to water availability

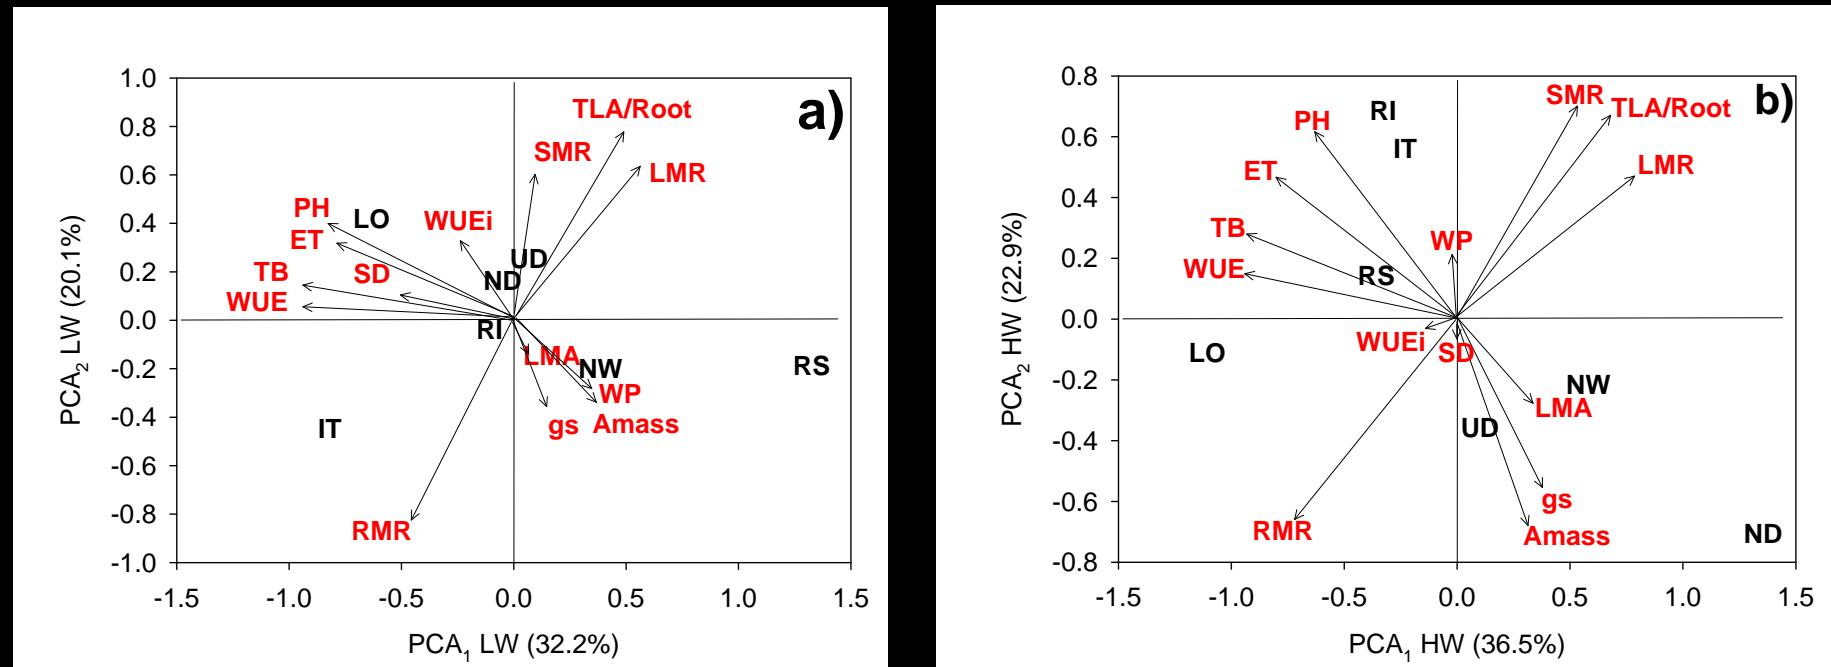

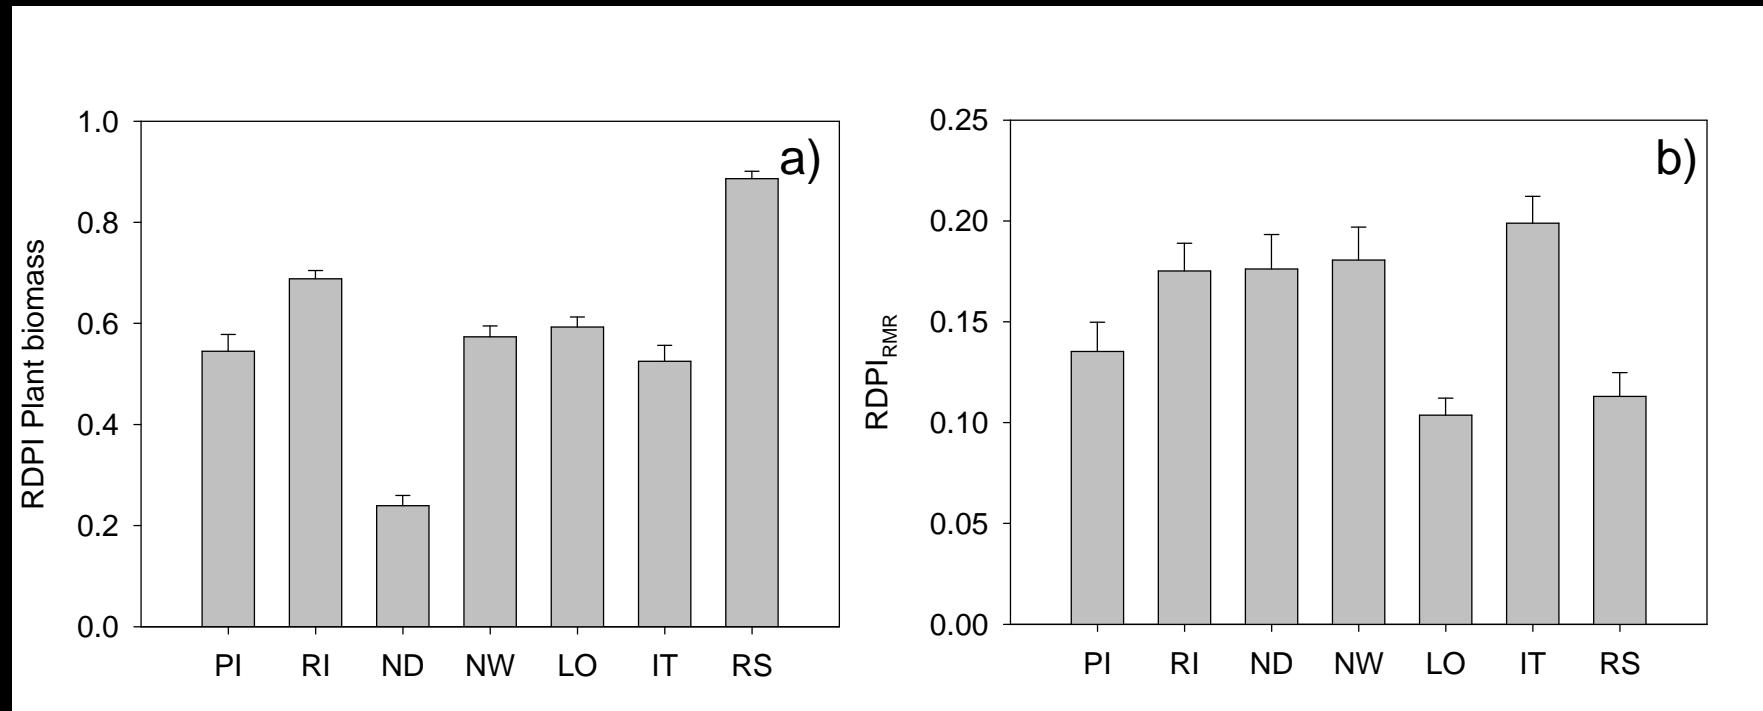

Figure 4. Principal component analysis (PCA) of all traits studied under low (LW) and high (HW) water availability. Mean population score is shown in each case. TB : Plant Biomass, PH: Plant height, WD: wood density, A_{mass} : Net photosynthetic rate per unit leaf mass, g_s : Stomatal conductance, WUEi: Instant water use efficiency, ET: Evapotranspiration, LMR: Leaf mass ratio, SMR: Stem mass ratio, RMR: Root mass ratio, TLA/Root: Total leaf area/root biomass, WP: Water potential, WUE: Water use efficiency, and LMA: Leaf mass per area

Measuring phenotypic plasticity

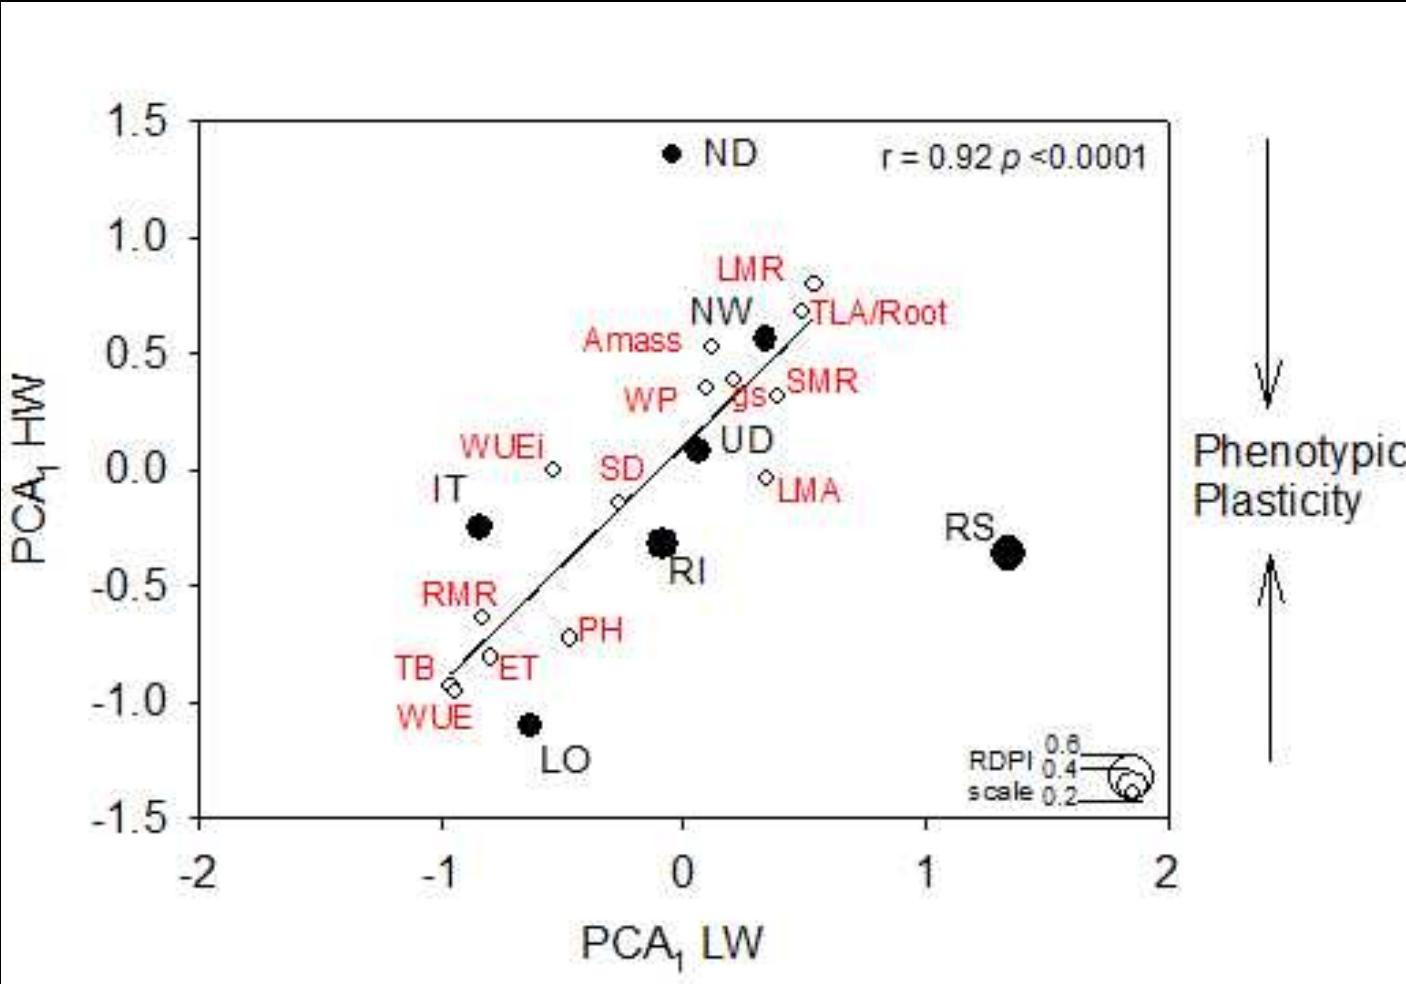

- RDPI = relative distance plasticity index

It is the mean value between the distance of each replicate of treatment 1 an treatment 2 divided by its sum

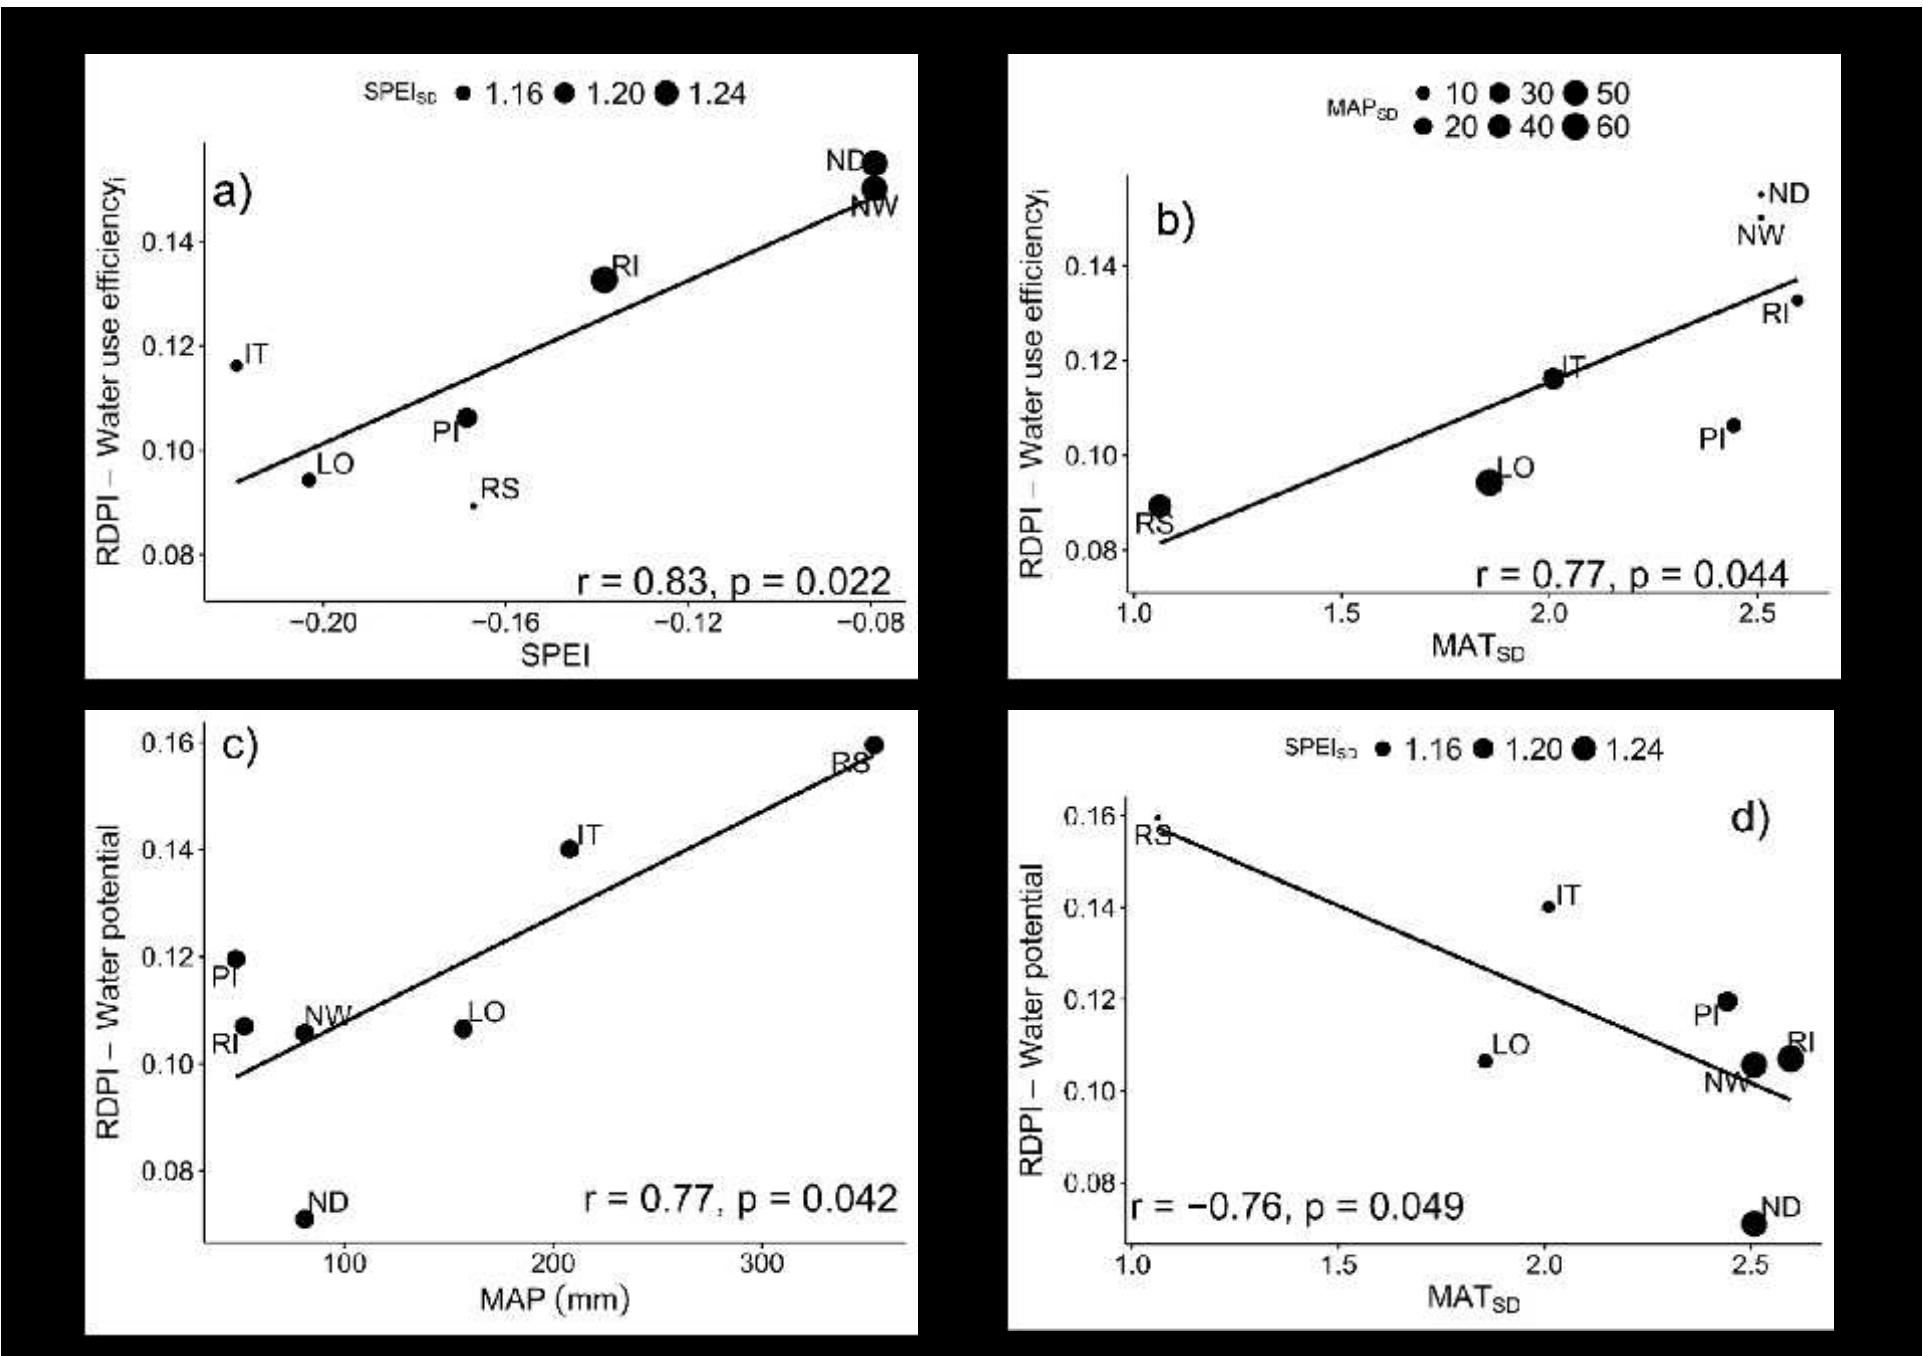

$$RDPI = \sum \left[\frac{(d_{ij} \rightarrow i'j')}{x_{ij} + x_{i'j'}} \right] / n$$

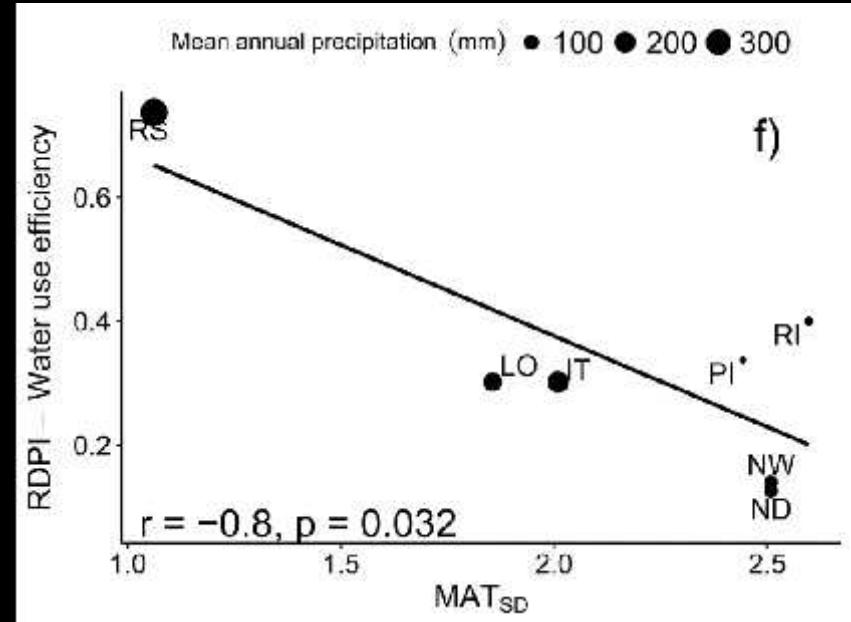

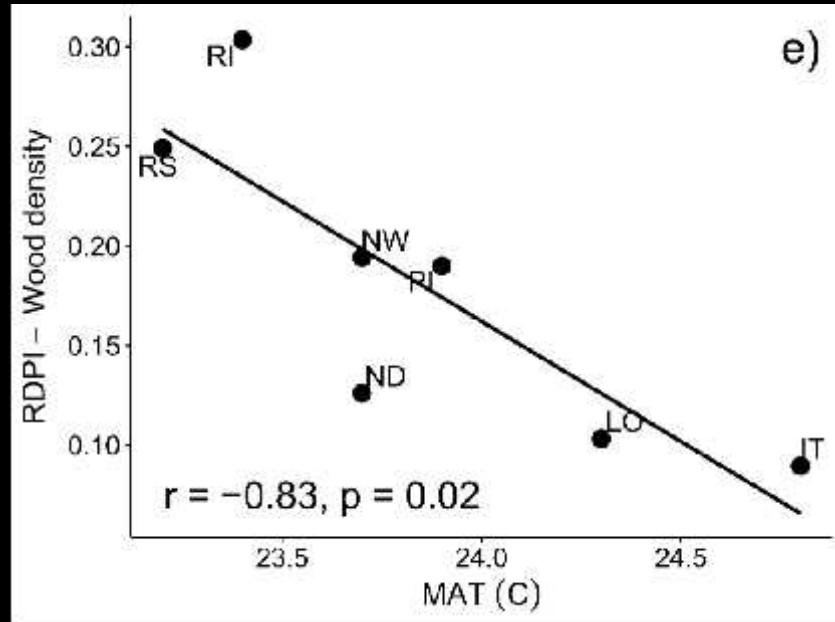

Plasticity index mean values (RDPI) per population. (a) Mean RDPI value of plant biomass per population. (b) Mean RDPI of root mass ratio (RMR) per population. Note the different scales of both figures

Relationships between the first axis of the principal component analysis (PCA) of traits under low (LW) and high (HW) water availability (PCA₁ HW versus PCA₁ LW). Correlation coefficient and statistical significance is shown. Black dots represent score values of each population, dots size are proportional to their mean RDPI

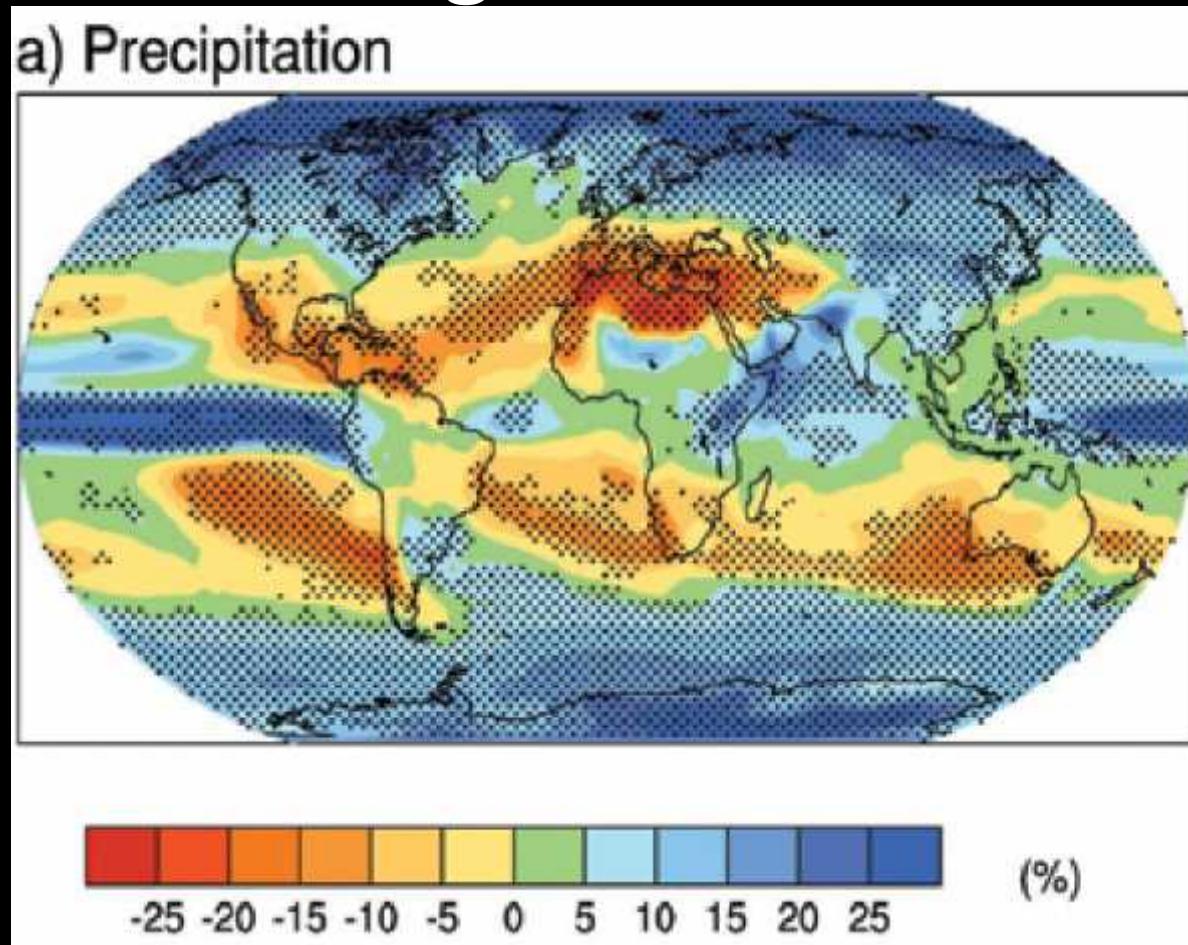

- Climatic factors has a significant effect on plastic plant physiology, but not in plant growth

- The *P. pallida* forest have a strong response to water availability, increasing **water consumption** and **plant biomass**
- RMR and LMA are key traits to increase plant biomass under high water availability
- Phenotypic plasticity is **limited** by co-trait variations

What it is expected under the climate change scenario?

Bates et al. Climate Change and water (2008)

What it is expected under the climate change scenario?

- An increase in sea surface temperature (1.5-2°C) is expect in the Pacific ocean
- Increase in mean annual rainfall?
- Increase in strong ENSO events
 - From 5 to 10 events each 100 years
- Infrastructural limitation to deal with ENSO

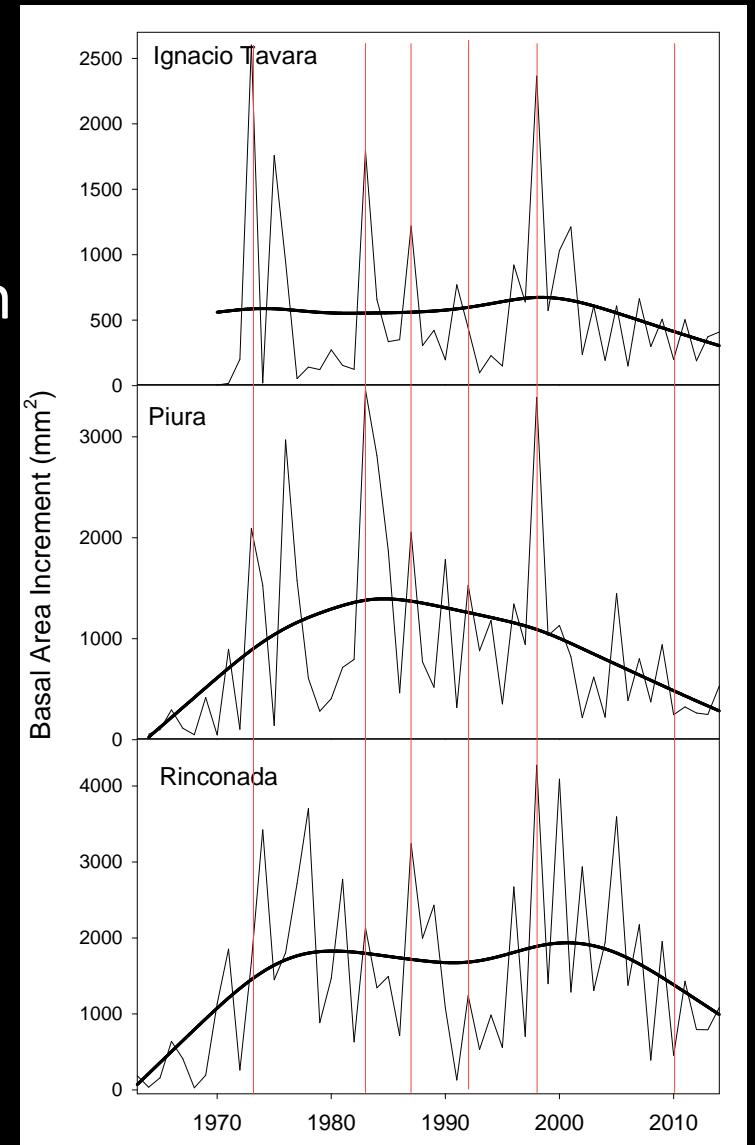

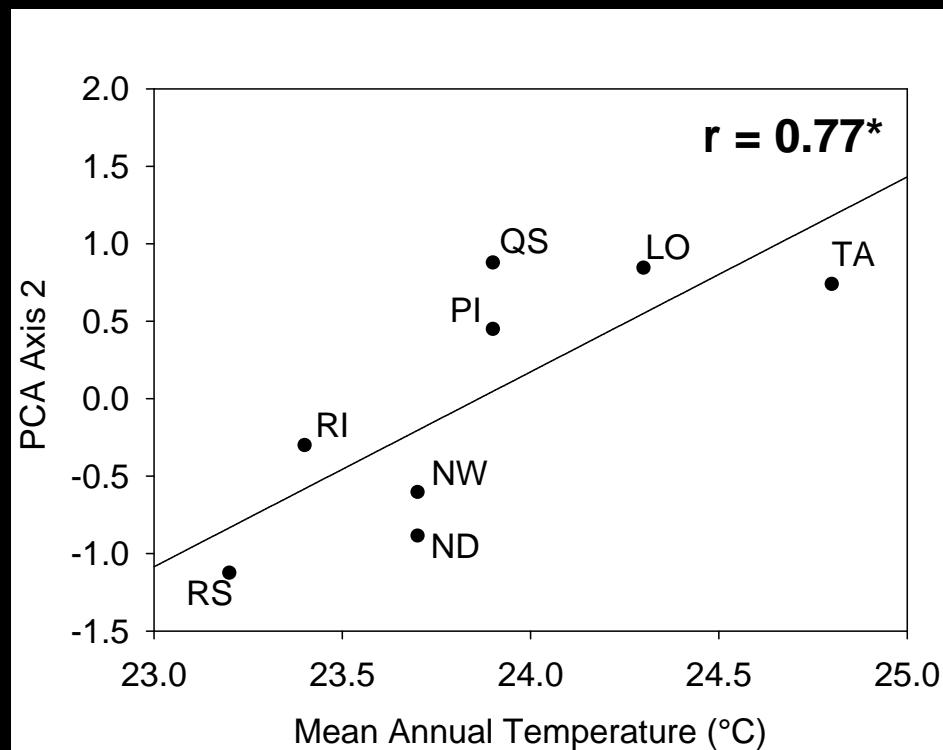

What it is expected under the climate change scenario?

- Infrastructural limitation to deal with ENSO

➤ What does this mean for the vegetation?

- ↑ Temperature → drier condition
- ↑ temperature → wetter condition

What it is expected under the climate change scenario?

- Increase in grass species during the wet seasons
- How resilient is the vegetation to deal with a fast dry and wet cycle?
- With a 99% sand soil, is runoff a problem?
- Increase in sand whirlwinds?
